ation and
undersaturation in
CdSe quantum dot
films as a function
of density of
donor states in
contact with the
quantum dots. We
study the
evolution of the
average number

of electrons in CdSe quantum dots (QDs) in contact with a semiconductor substrate as a function of the QD density in CdSe QD films deposited on a Si(111) substrate.

N-doped Si is used
as a model
substrate and InP
as a model
semiconductor.
The density of
states in the Si
host does not
increase linearly
with increasing
density of dopants

in the host, giving saturation of the QD occupation number for high densities of Si donors. We compare the situation of a single CdSe QD with the situation of CdSe/InP

heterostructures
in which case the
dopant density
increases linearly
with the density of
InP donors. The
differences
between these
two situations are
investigated by
extracting

electron-hole
Coulomb
correlation
corrections to the
energy of a single
CdSe QD from a
set of density-
functional-based
molecular
dynamics (MD)
simulations. The

occupation
number of an
isolated CdSe QD
shows remarkable
agreement with
the MD results at
a distance greater
than 1 nm to the
substrate. The
substrate-induced
charge transfer is

not effectively
screened by the
surrounding
crystal and results
in a net charge
accumulation of
approximately 0.4
e on the CdSe QD.
We show that the
net charge
accumulation is

very sensitive to
the effective
density of states
in the donor
material near the
valence band
edge (VBE). This
sensitivity gives
rise to the
characteristic
undersaturation of

the QD occupation number in low- density CdSe/InP QD films. 6d1f23a050
